

Module Code & Module Title

CS4051NT Fundamental of Computing

Assessment Weightage & Type

100% Individual Coursework

Year and Semester

2019-20 Spring

Student Name: Alisha Shrestha

London Met ID: 19033571

College ID: np05cp4s200028

Assignment Due Date: 20 September, 2020

Assignment Submission Date: 20 September, 2020

Word Count (Where Required): 6467

I confirm that I understand my coursework needs to be submitted online via Google Classroom under the relevant module page before the deadline in order for my assignment to be accepted and marked. I am fully aware that late submissions will be treated as non-submission and a mark of zero will be awarded.

Proposal

This proposal is written to address about the coursework of Fundamental of Computing Module which was assigned to us as an individual task. This coursework is all about developing a software application with python which demonstrates the integer addition based on binary operation. This coursework was provided on 3rd August and must be submitted on 20th September.

❖ Purpose

The purpose of this coursework is to write algorithm for the program in python which performs the integer addition based on binary operation. Suitable data structure is selected with the preparation of flow chart of the program. This task also includes writing the pseudocode of the program. The construction of model of the byte adder using electronic gates based on bit adder is included in the coursework.

❖ Targeted Audience

This program can be useful for the students, teachers, and programmers and for those who are interested in learning python programming language. This is for those who want to get the knowledge about how computer carries out mathematical operation.

❖ Hardware and Software Requirements

The software that is required to run the program was python 3 where as there is no specific requirements for hardware part for the completion of this task. Draw.io was used for construction logic gate and designing the flow chart. Logic.ly was used to design the model circuit of the 8 bit adder.

1. Introduction

Python is a high-level programming language designed to be easy to read and simple to implement as it is an open source, which means it is free to use, even for commercial applications. Scripts written in Python can be parsed and run immediately as well as they can also be saved as complied programs. (techterms)

Python is easy, simple to learn syntax and reduces the cost of program maintenance. Python encourages program modularity and code to be reused as it supports modules and packages. Python can run on every system like Mac, Window and UNIX. (ThePSF)

Some of the features of python programming language are:

- **Easy to code:**

Python is very easy to learn the language as compared to other languages such as C, C#, Java etc. It is very easy to code in python language and anybody can learn python basic in a few hours or mostly a day.

- **Free and open source:**

Python language is freely available at the official website and can be downloaded through the link provided in the page. The source code is also available to the public as it is an open source.

- **Object-oriented language:**

Like Java, Python is also Object-Oriented Programming language and it is the key feature of Python. Python supports Object-Oriented language and concepts of classes, etc.

- **High-Level Language:**

Python is a high-level language. When the programs are written in python there is no need to remember the system architectures or the management of memory.

- **Interpreted language:**

Python is an interpreted language as Python code is executed line by line at a time similar to other programming languages like C, C++, Java, etc. The Python code does not require to be compiled so that makes it much easier to debug the codes. The source code is converted into an immediate form called byte code. (GeeksforGeeks, 2020)

The history of the Python programming language dates back to the late 1980s and its implementation was started in December 1989 by Guido van Rossum at CWI in the Netherlands. Python's name is derived from the television series Monty Python's Flying Circus. Since 2003, Python has consistently ranked in the top ten most popular programming languages as measured by the TIOBE Programming Community Index. As of January 2016, it is in the fifth position. It was ranked as Programming Language of the Year for the year 2007 and 2010. It is the third most popular language whose grammatical syntax is not predominantly based on C.

Python is a widely used general-purpose, high-level programming language. Its design philosophy emphasizes code readability, and its syntax allows programmers to express concepts in fewer lines of code than would be possible in languages such as C++ or Java. The language provides constructs intended to enable clear programs on both a small and large scale. (Tulchak, 2016)

1.1 Introduction to Project

This is the report of the coursework that has been provided as a task of developing a program in Python programming language that mainly aims to convert binary number into decimal and decimal into binary. The function of this program is that it computes the sum of two integer's number based on binary operation and byte adder model is used for the process of addition. Moreover algorithm, pseudocode and flowcharts were made for developing this program. This project was about how the computer performs the addition operation of two integer number using 0 and 1. The process of addition was portrayed by the construction of byte adder model based on combination of eight bit adders with the help of logic gates. The flowchart was developed for demonstrating the flow and steps in the program. The task was performed in a very productive way within the time limit.

1.2 Aims

The aims of this project are:

- i. To carry out the entire task in the best possible way.
- ii. To accomplish the task of converting binary to decimal and decimal to binary in a simple way possible.
- iii. Plenty of research regarding process through which the computer performs addition of the integer numbers.
- iv. Acquiring the knowledge of algorithm and its uses in other projects.
- v. Gaining experience and skills of model circuit to implement.
- vi. Learning the actual mechanism behind the computer performing the process for conversion.

1.3 Objective

The major objectives of this project are:

- i. Construction of byte adder model based on the bit adder that would describe the process addition.
- ii. Writing the algorithm and pseudocode of the program that performs the operation.
- iii. Constructing a flowchart to show the arrangements of the steps for the completion of the program.
- iv. Writing a good program with the help of algorithm, pseudocode and flowchart for the conversion.
- v. Obtaining an accurate and versatile program by undergoing the chain of testing the program.

2. Model of Circuit Diagram

A model circuit diagram represents the actual electrical connections along with the arrangements of wire, bulbs and other components.

2.1 Working mechanism

To perform the task different logical gate is implemented that are AND gate, OR gate, XOR gate, NOT gate, NAND gate and XOR gate. In the logical get three inputs is taken which are upper bit, lower bit and Carry-in. The three inputs are passed to form one full bit adder in the same manner other seven full bit adder are also produced to make one full byte adder.

More precisely, looking into the functionality in detail of one full adder, there are three inputs upper bit, lower bit and Carry-in. The upper bit value and lower bit value is passed through XOR gate and AND gate(first AND gate), XOR gate and Carry-in value is passed through next AND gate (second AND gate). The first and second AND gate value is pass through NOR gate and the value obtain from that is again passed through NOT gate which produce first Carry-out of the full adder.

Here XOR gate value and Carry-in value is passed through NAND gate and OR gate. The value obtained from NAND and OR gate is again passed through AND gate which give the final sum of full adder.

With the whole procedure of full adder two values is obtained i.e. Carry-out and sum. The obtained value of Carry-out will be the Carry-in for the next adder likewise again three values i.e upper bit, lower bit and Carry-in will pass through full adder.

Similarly, the whole process is repeated for 8 times to form byte adder and after performing all the process a value is obtained that is considered as the sum which is the output produced from the logical gate of upper bit and lower bit.

For better understanding, two value is taken that are 77 and 127 but in logic gate the value in the form of 0s and 1s is only accepted so 77 and 127 is converted into binary form.

Table 1 Conversion of decimal into binary

Decimal number	Binary number
77	01001101
127	01111111
Total= 204	11001100

The above table demonstrates the conversion of decimal value to binary value. The last bit of the first binary number is considered as first upper bit i.e. 1, the last bit of the second given binary number is considered as first lower bit i.e. 1 and initially the first Carry-in value is 0 likewise the three value are passed into full adder similarly each values from the last is added in the full adder until it makes byte adder. The sum obtained from byte adder will be the output of two binary numbers.

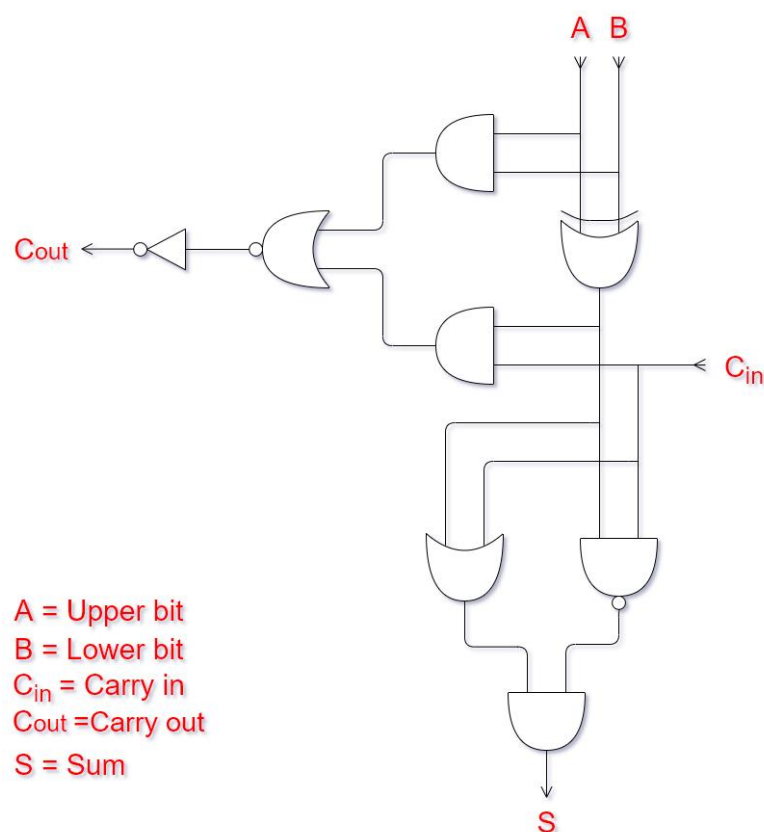

Figure 1 Full adder

Figure 2 Circuit diagram of 8 bit adder

The above figure illustrates the circuit diagram of 8 bit adder which is created on the basis of full adder. The circuit diagram not only illustrates the process of addition but it also shows the working procedure of full adder to give the sum. The full adder was produced with the help of the combination of different logic gates. Here in this circuit diagram the input provided to the full adder is denoted by rectangular box and sum obtained from each adder is denoted by bulb. Bulb with blue and white colour indicates 1 and 0 respectively.

2.2 Truth table of byte adder

Table 2 Truth table of byte adder

A	B	C _{in}	A xor B (xor)	A and B (and1)	xor and C _{in} (and2)	and1 nor and2 (nor)	nor not (C _{OUT})	xor nand C _{in} (nand)	xor or C _{in} (or)	xor and nand (Sum)
1	1	0	0	1	0	0	1	1	0	0
0	1	1	1	0	1	0	1	0	1	0
1	1	1	0	1	0	0	1	1	1	1
1	1	1	0	1	0	0	1	1	1	1
0	1	1	1	0	1	0	1	0	1	0
0	1	1	1	0	1	0	1	0	1	0
1	1	1	0	1	0	0	1	1	1	1
0	0	1	0	0	0	1	0	1	1	1

2.3 Parallel Circuit Diagram

Figure 3 Eight bit parallel circuit diagram

The above figure demonstrates the eight bit parallel circuit diagram. Here in this circuit diagram two binary values are passed for producing the sum of both the value. 77 and 127 is passed in the circuit diagram.

2.4 Logic gates

- **AND gate:** The AND gate is an electronic circuit that gives output 1 only if all its inputs are high. A dot is used to show the AND operation i.e. (A.B)

Figure 4 Circuit diagram of ANG gate

Table 3 Truth table of AND gate

Input		Output
A	B	A AND B
0	0	0
0	1	0
1	0	0
1	1	1

- **OR Gate:** The OR gate is an electronic circuit that produces a high output if one or more of its inputs are high. A plus is used to denote the OR operation i.e. (A+B).

Figure 5 Circuit diagram of Or gate

Table 4 Truth table of OR gate

Input		Output
A	B	A OR B
0	0	0
0	1	1
1	0	1
1	1	1

- **XOR Gate:** The XOR gate is a circuit which gives high output when the number of two inputs is odd. An encircled plus sign is used to represent XOR operation.

Figure 6 Circuit diagram of XOR gate

Table 5 Truth table of XOR gate

Input		Output
A	B	A XOR B
0	0	0
0	1	1
1	0	1
1	1	0

- **NOR Gate:** The NOR gate is an electronic circuit that produces a high output if both inputs are low or else all low.

Figure 7 Circuit diagram of NOR gate

Table 6 Truth table of NOR gate

Input		Output
A	B	A NOR B
0	0	1
0	1	0
1	0	0
1	1	0

- **NOT gate:** The NOT gate is an electronic circuit that where inputs are high then the output is low and if the input is low than the output is high.

Figure 8 Circuit diagram of NOT gate

Table 7 Truth table of NOT gate

Input	Output
A	A NOT B
0	1
1	0

- **NAND gate:** The NAND gate is an electronic circuit that produces a low output if both inputs are high or else the output is high.

Figure 9 Circuit diagram of NAND gate

Table 8 Truth table of NAND gate

Input		Output
A	B	A NAND B
0	0	1
0	1	1
1	0	1
1	1	0

3. Algorithm

An algorithm is a set of well-defined instructions in step by step manner to solve a particular problem. In other word it is a set of rule which explains how a problem can be solved in steps. An algorithm should not include computer code and it must be written in such a way that it can also be useful in different programming languages. An algorithm must be composed of a finite set of steps where each may require one or more operation. (Kullabs, 2019)

The good algorithm should have the following features:

- Input: It must specify and requires input values.
- Output: It must determine outcome values or solution of the problem.
- Definite: It must define each process and the progress clearly.
- Effective: It must be more effective among many different ways to solve a problem.
- Finite: It must consist of finite number of steps and operations. (laps)

Example of algorithms in programming while adding two numbers entered by the user:

Step 1: Start

Step 2: Declare variables num1, num2 and sum.

Step 3: Read values num1 and num2

Step 4: Add num1 and num2

Step 5: Display sum

Step 6: Stop (Kullabs, 2019)

Writing the algorithm for the program:

Step 1: Start

Step 2: Ask user to input binary or decimal number

Step 3: If user input binary number

Step 3.1: Ask first binary number

Step 3.2: If first input is less than 0 or more than 255 repeat Step 3.1

Step 3.3: Ask second binary number

Step 3.4: If second input is less than 0 or more than 255 repeat Step 3.3

Step 3.5: Add two binary numbers

Step 3.6: If the output of two binary numbers is less than 0 or more than 255

repeat Step 3.1

Step 3.7: Convert binary into decimal number

Step 3.8: Display the output of both binary and decimal number

Step 4: If user input decimal number

Step 4.1: Ask first decimal number

Step 4.2: If first input is less than 0 or more than 255 repeat Step 4.1

Step 4.3: Ask second decimal number

Step 4.4: If second input is less than 0 or more than 255 repeat Step 4.3

Step 4.5: Add two decimal numbers

Step 4.6: If the output of two binary numbers is less than 0 or more than 255

repeat 4.1

Step 4.7: Convert decimal into binary number

Step 4.8: Display the output of both decimal and binary number

Step 5: Ask user to continue program or not

Step 5.1: If user want to continue program then repeat from step 2

Step 5.2: if user doesn't want to continue than it goes to step 6

Step 6: Stop

4. Pseudocode

Pseudocode is an informal manner of writing the description of a program with no strict syntax like in programming language. Pseudocode is not considered as an actual programming language because it does not get compiled into an executable program. It is very simple and easy to write because it uses short terms and minor English language syntaxes to write the code for the programs before the code is converted into any specific program. Pseudocode holds detailed and readable information about the program so that make easier for the process of developing a program. Pseudocode provides a good summary on the flow of the program and algorithm of the program in a very effortless manner. (Rouse, 2005)

Pseudocode is helpful for the programmer because catching errors and wrong program flow at the pseudocode stage becomes less costly than catching them later in the development process. It is also possible to write programs that will convert a given pseudocode language into a given programming language. Pseudocode enables the programmer to concentrate only on the algorithm part of the code development as it is used in planning an algorithm with sketching out the structure of the program before the actual coding takes place. The program description and the functions are collected and then the pseudocode is used to create statements to achieve the required results for a program. (The Economic Times, 2020)

5. Flowchart

A flowchart is simply a graphical representation of step by step solution of a problem. Flowchart is symbols whereas algorithms and pseudocode are text-based method of designing programs. They help us visualize complex processes, or make explicit the structure of problems and tasks. It shows steps in sequential order and is widely used in presenting the flow of algorithms also it is the regarded as the oldest techniques to depict an algorithm and its workflow or processes. (Kullabs, 2019)

It was originated from computer science as a tool for representing algorithms and programming logic but had extended to use in all other kinds of processes. A flowchart also makes debugging process easier which can be a gift for programmers. A flowchart shows the steps as boxes of various kinds, and their order by connecting them with arrows. Different flowchart shapes have different conventional meanings. (Paradigm)

The basic flowchart symbols are designed and meanings of some of the more common shapes are as follows:

- a) Terminator: This oval shaped symbol represents the starting or ending point of the system which are written in the beginning and end in flowchart.

Figure 10 Terminator

- b) Input/output: A parallelogram indicates the function of input/output.

Figure 11 Input/ Output

- c) Process: This rectangular box indicates arithmetic operations, processes and data manipulations.

Figure 12 Process

- d) Decision making: A diamond represents a decision or branching point. Lines coming out from the diamond indicate different possible situations, leading to different sub-processes.

Figure 13 Decision making

- e) Connector: A circle symbol in the flowchart is helpful to utilize the connector to stay away from any confusion.

Figure 14 Connector

- f) Flow: Lines represent the flow of the sequence and direction of a process.

Figure 15 Flow

Example of a flowchart: Sum of 529 and 256

Figure 16 Example of Flowchart

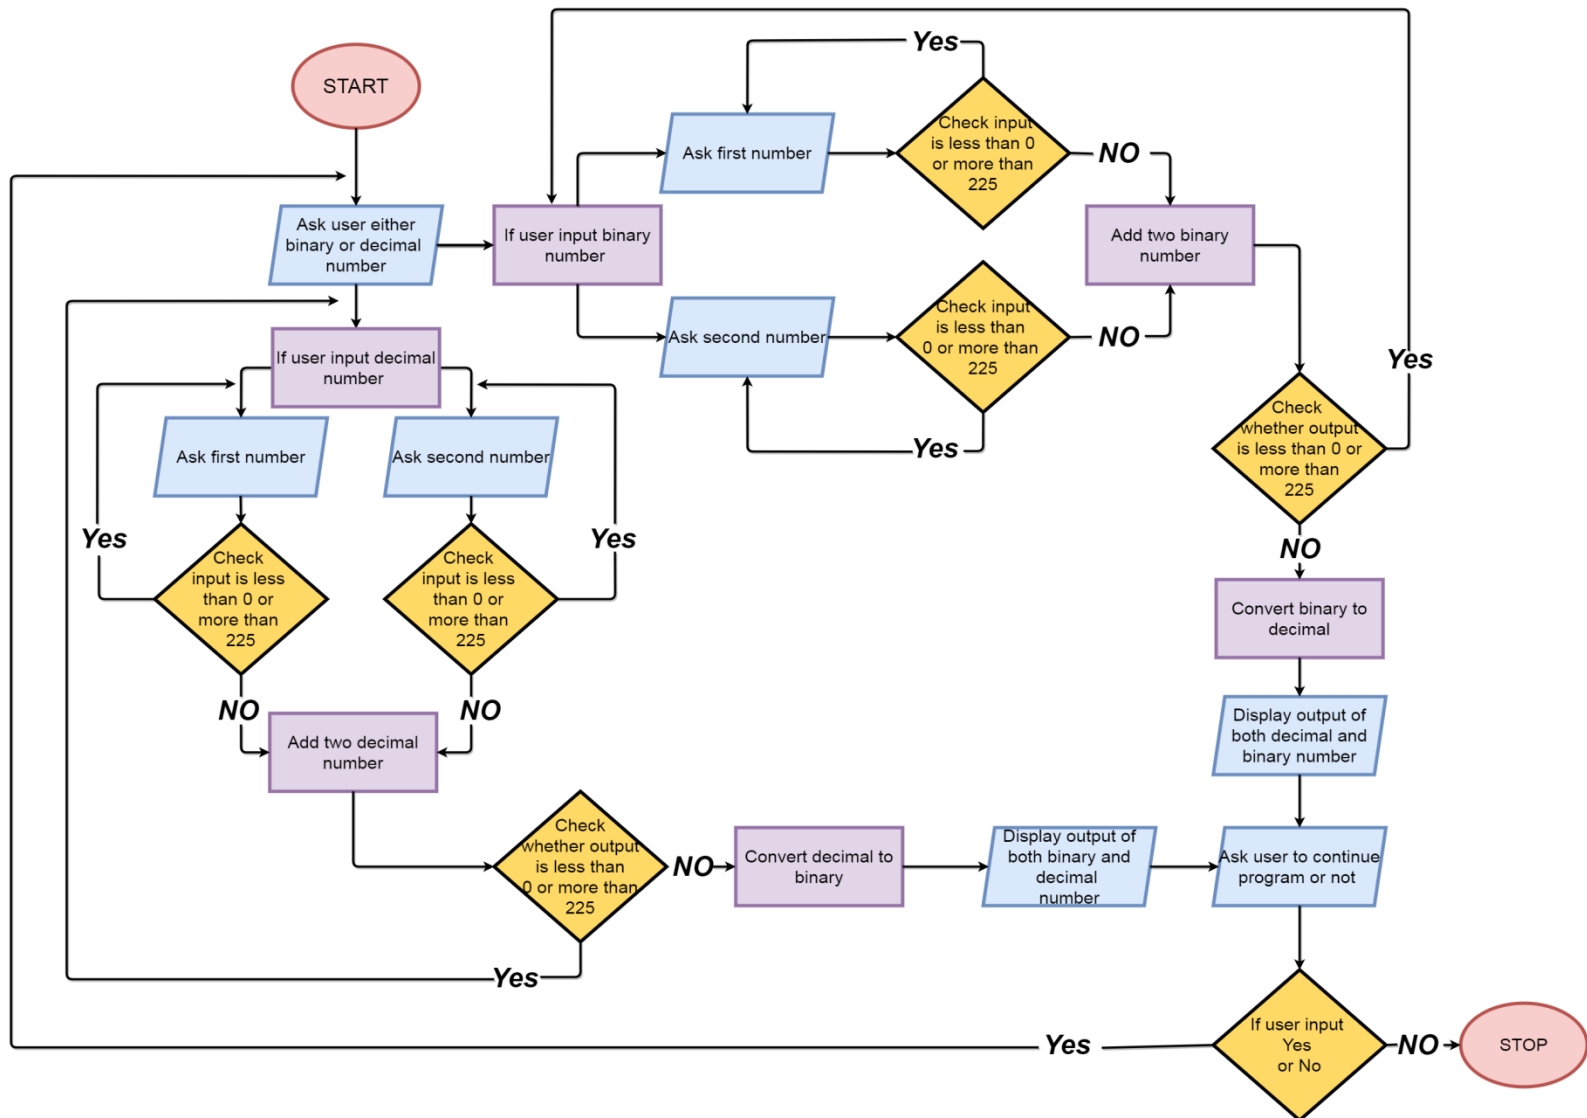

Figure 17 Flow chart of 8 bit adder

6. Data Structure

Python has been used worldwide for different fields but to make this possible data plays a very vital role where data should be stored efficiently so managing, organizing and storing data is important. Data structure makes easier access and efficient modifications of data as it enables to store collections of data, related and perform operations on those data accordingly. (StudyTonight)

Python allow to create own data structure with the functionality and it enables user to control the functionality. Python provides varieties of data types such as integer, string, Boolean etc. Python has a host of in-built data structures that help us to easily organize our data

In python there are two data structures i.e. Primitive data structure and Non- primitive data structure. (Akash, 2019)

6.1 Primitive data structures

Primitive data structure is the most basic data structure and they are the building blocks for the data manipulation. The types of primitive data structures used in this project are:

- **Integers:**

Integer is a numeric data which holds whole numbers from negative to positive. Integer is also written as 'int' which does not have decimal points and this data type has no limit for the value as it holds infinite integer value until the system memory can hold. Any numeric value can be added as integer value. (Jaiswaly)

For example:

```
a = 5
```

```
print(a "is a integer.")
```

Output:

```
5 is an integer.
```

In this project integer data type is used to store the integer values. . The number input by the user is in string so it is converted into integer value in `asinput.py` module. The sum obtained from the addition of two numbers is used as integer value In **`asinput.py`**, **`forconversion.py`**, **`validation.py`** and **`foradder.py`** module integer data type is used for storing the integer value.

- **String:**

String is a sequence of one or more characters which is written inside single quotation mark or double quotation mark. It stores both constants or variables and it is enclosed with single or double quotation but only one type should be used throughout the program. In python the quotes represents the beginning and ending of the string. The string data type in python can be converted in to other data types by using various in-built function provided by python. String can hold as many characters as the users wants because it stores until the system memory can hold. (geeksforgeeks)

For example:

```
a = "This is Python."  
print(a)
```

Output:

This is Python.

In this project string data type is used in `foradder.py` module to add the sum of two binary numbers. In the `main.py` module string data type is used to obtain the decision from the user for either continuing the program or end the program. In `asinput.py` module string data type is used to obtain a single string value which is input by the user in variable for the purpose of storing the binary values of the string.

6.2 Non- primitive data structure

Non-primitive data structures are the complicated members of the data structure family.

It does not only store the value but its stores collection of values in various formats.

The types of non-primitive data structures used in this project are:

- **List:**

In python list is a well-organized sequence of items which is considered as the most used data type in python. It is declared by separating the items with commas and enclosing inside the square brackets. List can make changes in their content without changing the identity. Python has many methods to work with lists changes can also be made during the time of execution as per the requirements. Even the size of list can also be changed so overall list is considered as very flexible data structure. (Jaiswaly)

For example:

```
a = [1,2,3]
```

```
print(a)
```

Output:

```
[1,2,3]
```

In this project list was used in foradder.py module to store 8 bit binary number.

- **Dictionary:**

Dictionary is an unordered collection of huge amount of data values which is used to store data values. Dictionary holds key: value pair as it is used to make it more optimized. In Python, a dictionary is declared by separating elements by commas and enclosed in curly braces. It holds a pair of values where one value is considered as the key and other as key: value. Any data type can be used in dictionary and the keys cannot be repeated or changed.

Dictionary keys are case sensitive so the elements with same name but eith different cases are not considered same. (Programiz)

For example:

```
a= {"number" : 1, "Name" : Python}
```

```
print(a[number])
```

```
print(a[Name])
```

Output:

1

Python

7. Program

7.1 Main module

```
# main.py module controls all the module to complete the conversion of binary and decimal number
# It import the asInput module to perform user interaction.
# Author: Alisha Shrestha, 10 September, 2020

from asinput import *

# Creating the function to make its user experience better
def main_function():
    # Making a design of 8 bit adder
    print("_____ ~ Python ~ _____")
    print(":")
    print(":")
    print(": 8 BIT ADDER")
    print(":")
    print(":")
    print(":")
    print(":")
    print(":")
    print("_____ ~~Alisha Shrestha~~ _____")
    print()
    binary_decimal_input() # calling function
    check = False # initializing False boolean value
    # while loop is created to check the condition until user input correct value
    while(not check):
        print()
        # it ask user to input value
        exit_input = input("Do you want to continue [Yes/No] : ")
        print()
```

Figure 18 Screenshot no 1 of main.py module

```
# lower() method is used to return the lowercased string
# it converts all uppercase character to lower case
if (exit_input.lower() == "yes"):
    binary_decimal_input()
elif (exit_input.lower() == "no"):
    print()
    print("Thank you for using this program.")
    print()
    check = True
else:
    print("Error !!! , Please enter Yes to run the program or No to exit program.")

main function()
```

7.4 Conversion module

forconversion.py module is created to covert binary and decimal number
Author: Alisha Shrestha, 10 September, 2020

Creating function to convert binary into decimal

```
def bin_to_dec(value):  
    dec_no = 0  
    i = 0  
    while (value > 0):  
        last_no = value % 10  
        dec_no += last_no * (2 ** i)  
        i += 1  
        value = int(value/10)  
    return dec_no  
##print(bin_to_dec(11111111))
```

Creating function to convert decimal into binary

```
def dec_to_bin(value):  
    list_of_eightbit = ["0","0","0","0","0","0","0","0"]  
    index_ = 7  
    while (value > 0):  
        b = value % 2  
        list_of_eightbit[index_] = str(b)  
        index_ -= 1  
        value = int(value/2)  
    return "".join(list_of_eightbit)  
##print(dec_to_bin(12))  
##print(dec_to_bin(176))
```

Figure 26 Screenshot of forconversion.py module

7.5 Adder module

```

# foradder.py module is created to add the two binary number
# It import gates module to operate logical gates

from gates import *

# Creating adder gate function to add two number
def adder_gate(bin_no1,bin_no2):
    carry = 0 # initial carry is 0
    list_of_eightbit = ["0","0","0","0","0","0","0","0"] # Creating the list of 8 bits

    # Creating the iterator of range start, stop and step
    for a in range (7,-1,-1):
        upper_bit =int(bin_no1[a]) # upper bit value going through iteration
        lower_bit = int(bin_no2[a]) # lower bit value going through iteration

        xor_ = xor_gate(upper_bit, lower_bit) # call xor_gate function
        nand_ = nand_gate(xor_,carry) # call nand_gate function
        or_ = or_gate(xor_,carry) # call or_gate function
        sum_of_bit = and_gate(or_,nand_) # call and_gate function

        list_of_eightbit[a] = str(sum_of_bit)

        and_no1 = and_gate(upper_bit, lower_bit)
        and_no2 = and_gate(xor_, carry)
        carry = not_gate(nor_gate(and_no1, and_no2))

    # return 8 bit binary number after going through logical circuit
    return "".join(list_of_eightbit)

```

Figure 27 Screenshot of foradder.py module

7.6 Validation.py module

validaiton.py module is created for validation of binary and decimal number.
 # Author: Alisha Shrestha, 10 September, 2020

```
# creating function for binary validation.
def binary_validation(input_bin):
    if (input_bin == ""): # it check empty value
        return [True, "Error !!! Please enter the value."]

    # try and except is used to handle the exception
    try:
        check = int(input_bin) # it check whether the value is integer type or not
    except:

8. Conclusion

To wrap up the overall documentation of this project many difficulties were faced throughout but many researches were also done to overcome those difficulties. This was the very first coursework in Python programming Language, though this was the first but after doing lots of researches and practices it was found that this programming language was much simpler than other programming languages and also this was fun as well.

In order to complete the report for the whole project all the procedure were included in the report with necessary screenshots, description etc. for more clarification. Many researches were carried out for successful completion of this task and researches were done on the relevant topics such as byte adder, algorithm, pseudocode, flowchart, data structure, circuit diagram, testing the program etc.

As a first step, model circuit was constructed where 8 bit adder and parallel circuit were prepared along with the selection of a data structure for writing the program. In the same manner as the next step algorithm and pseudocode of the program was written. With the completion of algorithm and pseudocode flow chart is prepared for describing the flow of the program. After the coding part testing is performed to ensure about the program is providing accurate output or not.

The main focus of this project was integer addition based on the binary and decimal operation including the conversion of binary and decimal number. Data structure also helped in storing data, organizing data and operation performed in the program.

This project was not only the college assignment but it was more like a practice for performing the individual task with much ease and effectively which will be very useful for the future projects in the real world. The main plus point for this coursework was of learning a different programming language and implementing that into something useful and creative.

The concept while getting involved in this project was first focused on only completing the task but later on it got more interesting day by day as it was fun to code and easy to implement, moreover the algorithm, pseudocode and flow chart made it easier to

develop the program. The other benefit of this task in practical life was that many technical words got familiar and that was only possible due to lots of research. Another interesting finding was learning about how the computer computes the sum of two integer value. This project was not easy for completing but it was done with all the hard work and research.

8.1.1 Website

- i. [https://whatis.techtarget.com/definition/logic-gate-AND-OR-XOR-NOT-NAND-NOR-and-XNOR#:~:text=A%20logic%20gate%20is%20a,\)%20or%20true%20\(low\).](https://whatis.techtarget.com/definition/logic-gate-AND-OR-XOR-NOT-NAND-NOR-and-XNOR#:~:text=A%20logic%20gate%20is%20a,)%20or%20true%20(low).)

The screenshot shows the TechTarget website interface. At the top, there is a teal navigation bar with the TechTarget logo, 'Whatis.com', and links to 'BROWSE DEFINITIONS Electron...' and 'QUICK STUDY Resources'. A search bar on the right says 'Search Thousands of Tech Definitions'. Below the navigation bar, a breadcrumb trail reads: 'Home > Topics > Computer Science > Electronics > logic gate (AND, OR, XOR, NOT, NAND, NOR and XNOR)'. The main content area has a 'DEFINITION' header. On the left, there is a vertical sidebar with social media icons (Facebook, Twitter, LinkedIn, etc.). The main title is 'logic gate (AND, OR, XOR, NOT, NAND, NOR and XNOR)'. The definition text states: 'A logic gate is a building block of a digital circuit. Most logic gates have two inputs and one output and are based on Boolean algebra. At any given moment, every terminal is in one of the two binary conditions false (high) or true (low). False represents 0, and true represents 1. Depending on the type of logic gate being used and the combination of inputs, the binary output will differ. A logic gate can be thought of like a light switch, wherein one position the output is off—0, and in another, it is on—1. Logic gates are commonly used in integrated circuits (IC).' Below this, a section titled 'Basic logic gates' says 'There are seven basic logic gates: AND, OR, XOR, NOT, NAND, NOR, and XNOR.' At the bottom of the definition section, there are links: 'AND | OR | XOR | NOT | NAND | NOR | XNOR'. On the right side of the page, there is a profile for 'Margaret Rouse' with social media links and a 'Word of the Day' section. A large advertisement for 'SKILLS DEVELOPMENT GUIDE' is also visible on the right, with the text 'Now is the time to evaluate what type of training you really need.' and a 'DOWNLOAD NOW' button.

Proven Reliability

Explanation of Half Adder and Full Adder with Truth Table

An adder is a **digital logic circuit** in electronics that is extensively used for the addition of numbers. In many computers and other types of processors, adders are even used to calculate addresses and related activities and calculate table indices in the ALU and even utilized in other parts of the processors. These can be built for many numerical representations like excess-3 or binary coded decimal. Adders are basically classified into two types: Half Adder and Full Adder.

What is Half Adder and Full Adder Circuit?

Data Structures

A **data structure** is a particular way of organizing data in a computer so that it can be used effectively.

For example, we can store a list of items having the same data-type using the *array* data structure.

We know that computer is user dependent machine. It doesn't work or think on its own. All the activities of computer system are controlled and processed by the instructions and information provided by the user. These instruction are called commands. Collection of such instruction and the data in a systematic form to solve the problem is called the program.

To solve the problem using computer we have to make some systematic plan of action. Such plan of action can be represented in the systematic order using different tools and technique called the program presentation tools and technique. Popular tools and technique used to represent the programs are flowchart and algorithm.

Algorithm

Algorithm is defined as a set of rules that define how a particular problem can be solved in finite number of steps. In another word, algorithm is a step by step representation of instructions to solve the problem. An algorithm must be composed of a finite set of steps, each of which may require one or more operations.

The good algorithm should have following features:

The screenshot displays the DataCamp website interface. On the left is a blue sidebar with navigation links: DataCamp logo, COMMUNITY, News (BETA), Tutorials, Cheat Sheets, Open Courses, Podcast - DataFramed, Chat (NEW), DATACAMP, Official Blog, Resource Center, Upcoming Events, and a Subscribe to RSS link. At the bottom of the sidebar are social media icons for Facebook, Twitter, LinkedIn, and YouTube, along with links for About, Terms, and Privacy. The main content area features a search bar, a 'Log in' button, and a 'Create Free Account' button. Below these is a user profile for Sejal Jaiswal, dated December 8th, 2017, with a 'PYTHON' tag. The title 'Python Data Structures Tutorial' is prominently displayed. The introductory text reads: 'Get introduced to Python data structures: learn more about data types and primitive as well as non-primitive data structures, such as strings, lists, stacks, etc.' To the left of the text are engagement metrics: 77 comments and 156 likes. Below the text is a green Python logo, a promotional banner for DataCamp stating 'GAIN THE CAREER-BUILDING PYTHON SKILLS YOU NEED WITH DATACAMP' with a 'Start Learning Now' button, and social media sharing icons for Facebook, Twitter, and LinkedIn. The final paragraph explains that data structures are a way of organizing and storing data for efficient access and operations, noting that many various kinds of data structures are defined to make this easier.

The screenshot displays the Economic Times website's definition page for 'Pseudocode'. The page layout includes a top navigation bar with sections like ET Prime, Markets, News, and more. Below this is a search bar and a 'Stock Screener' section. The main content area features the title 'Definition of 'Pseudocode'' under the 'Software-Development' category. It includes a 'Definition' paragraph explaining that pseudocode is an informal programming description, and a 'Description' paragraph stating it is not an actual programming language. To the right, there is a 'Not to be Missed' section with links to news articles like 'The Farmers' Produce Trade and Commerce (Promotion and Facilitation) Bill, 2020' and 'The future ahead'. The page also includes social media sharing icons on the right side.

Definition of 'Pseudocode'

Definition: Pseudocode is an informal way of programming description that does not require any strict programming language syntax or underlying technology considerations. It is used for creating an outline or a rough draft of a program. Pseudocode summarizes a program's flow, but excludes underlying details. System designers write pseudocode to ensure that programmers understand a software project's requirements and align code accordingly.

Description: Pseudocode is not an actual programming language. So it cannot be compiled into an executable program. It uses short terms or simple English language syntaxes to write code for programs before it is actually
